Generalization of Difference Formulas

• In general, a difference approximation to the m^{th} derivative at grid point j can be cast in terms of q + p + 1 neighboring points as

$$\left(\frac{\partial^m u}{\partial x^m}\right)_j - \sum_{i=-p}^q a_i u_{j+i} = er_t \tag{1}$$

where the a_i are coefficients to be determined through the use of

• Forward, backward, skewed, or central point operators of any order for any derivative.

Compact Difference Formulas

• A generalization of Eq. 1 can include derivatives at neighboring points, i.e.,

$$\sum_{i=-r}^{s} b_i \left(\frac{\partial^m u}{\partial x^m} \right)_{j+i} - \sum_{i=-p}^{q} a_i u_{j+i} = er_t$$
 (2)

• An example of such a formula written on terms of general coefficients a, b, c, d, e is

$$d\left(\frac{\partial u}{\partial x}\right)_{j-1} + \left(\frac{\partial u}{\partial x}\right)_{j} + e\left(\frac{\partial u}{\partial x}\right)_{j+1} - \frac{1}{\Delta x}(au_{j-1} + bu_{j} + cu_{j+1}) = er_{t}$$

• Here not only is the derivative at point j represented, but also included are derivatives at points j-1 and j+1 which also must be expanded using Taylor series about point j.

• Requires generalization of the Taylor series expansion

$$\left(\frac{\partial^m u}{\partial x^m}\right)_{j+k} = \left\{ \left[\sum_{n=0}^{\infty} \frac{1}{n!} (k\Delta x)^n \frac{\partial^n}{\partial x^n} \right] \left(\frac{\partial^m u}{\partial x^m}\right) \right\}_j$$
(3)

• Derivative terms now have coefficients which must be determined using the Taylor table approach as outlined below.

Taylor Table for Compact Difference Formulas

Taylor Table for Compact Difference Formulas

- Maximize the order of accuracy
- Set the first five columns to zero producing the matrix equation for the coefficients,

$$\begin{bmatrix} -1 & -1 & -1 & 0 & 0 \\ 1 & 0 & -1 & 1 & 1 \\ -1 & 0 & -1 & -2 & 2 \\ 1 & 0 & -1 & 3 & 3 \\ -1 & 0 & -1 & -4 & 4 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \\ d \\ e \end{bmatrix} = \begin{bmatrix} 0 \\ -1 \\ 0 \\ 0 \end{bmatrix}$$

• Having the solution $[a, b, c, d, e] = \frac{1}{4}[-3, 0, 3, 1, 1].$

• Under these conditions, the sixth column sums to

$$er_t = \frac{\Delta x^4}{120} \left(\frac{\partial^5 u}{\partial x^5}\right)_j$$

- A 4th order accurate method
- The method can be expressed as

$$\left(\frac{\partial u}{\partial x}\right)_{j-1} + 4\left(\frac{\partial u}{\partial x}\right)_j + \left(\frac{\partial u}{\partial x}\right)_{j+1} - \frac{3}{\Delta x}(-u_{j-1} + u_{j+1}) = O(\Delta x^4)$$

- Obviously, the implementation of such a method requires more explanation.
- Matrix forms of difference schemes will be useful.
